Analyzing Blockwise Lattice Algorithms using Dynamical Systems

- Lattices provide exponentially hard problems suitable for public key cryptography.
- Best known attacks on lattice-based cryptosystems rely on blockwise lattice reduction algorithms.
- Understanding these algorithms helps assessing the security of LBC.
- The most widely used reduction algorithm is BKZ.
- No reasonable time bound was known about BKZ.

Contributions

- We give the first worst-case analysis of BKZ.
- We introduce a new BKZ model.
- It gives new tools for understanding lattice algorithms.

Experience on 64 LLL-reduced knapsack-like matrices ($n = 108, \beta = 24$).

э

Our result

 $\gamma_{\beta} = \text{Hermite constant} \leq \beta.$ L a lattice with basis (b_1, \dots, b_n) .

Theorem
After
$$\mathcal{O}\left(\frac{n^3}{\beta^2}\left(\log\frac{n}{\epsilon} + \log\log\max\frac{\|b_i\|}{(\det L)^{1/n}}\right)\right)$$
 calls to HKZ_{β} ,
 BKZ_{β} returns a basis C of L such that:
 $HF(C) \leq (1 + \epsilon)\gamma_{\beta} \frac{n-1}{2(\beta-1)} + \frac{3}{2}$.

Analyzing Blockwise Lattice Algorithms using Dynamical Systems

Sandpile model

• We consider only $x_i = \log ||b_i^*||$ for $i \le n$.

- We assume that HKZ-reductions correspond to a fixed pattern.
- The information on the initial x_i's fully determines the x_i's after a call to HKZ.

Sandpile model

- We consider only $x_i = \log ||b_i^*||$ for $i \le n$.
- We assume that HKZ-reductions correspond to a fixed pattern.
- The information on the initial x_i's fully determines the x_i's after a call to HKZ.

Quality of the output

Method: study the fixed point of:

$$X = AX + \Gamma$$

- The β last x_i 's have the shape of an HKZ-reduced basis.
- Asymptotically, line of slope $-\frac{\log \gamma_{\beta}}{\beta-1}$.

Quality of the output

Method: study the fixed point of:

$$X = AX + \Gamma$$

- The β last x_i 's have the shape of an HKZ-reduced basis.
- Asymptotically, line of slope $-\frac{\log \gamma_{\beta}}{\beta-1}$.

Quality of the output

Method: study the fixed point of:

$$X = AX + \Gamma$$

- The β last x_i 's have the shape of an HKZ-reduced basis.
- Asymptotically, line of slope $-\frac{\log \gamma_{\beta}}{\beta-1}$.

Fast convergence

Dynamical system:

$$X \leftarrow AX + \Gamma$$

Method: study of the eigenvalues of $A^T A$.

Result: the largest eigenvalue of $A^T A$ smaller than 1 is

$$\leq 1-\frac{1}{2}\frac{\beta^2}{n^2}.$$

 $\|X - X^{\infty}\|$ decreases by a constant factor every $rac{n^2}{\beta^2}$ tours. ightarrow leads to the claimed complexity bound.

Fast convergence

Dynamical system:

$$X \leftarrow AX + \Gamma$$

Method: study of the eigenvalues of $A^T A$.

Result: the largest eigenvalue of $A^T A$ smaller than 1 is

$$\leq 1-\frac{1}{2}\frac{\beta^2}{n^2}.$$

 $||X - X^{\infty}||$ decreases by a constant factor every $\frac{n^2}{\beta^2}$ tours. \rightarrow leads to the claimed complexity bound.

Dynamical system:

$$X \leftarrow AX + \Gamma$$

Method: study of the eigenvalues of $A^T A$.

Result: the largest eigenvalue of $A^T A$ smaller than 1 is

$$\leq 1 - \frac{1}{2} \frac{\beta^2}{n^2}.$$

 $||X - X^{\infty}||$ decreases by a constant factor every $\frac{n^2}{\beta^2}$ tours. \rightarrow leads to the claimed complexity bound.

Analyzing Blockwise Lattice Algorithms using Dynamical Systems

From the model to the real algorithm

- The results from the previous section cannot be used directly.
- By averaging the x_i's, a rigorous adaptation becomes possible.
- Working on the averages suffices to get the result.
