Outline

Preimages using meet-in-the-middle techniques

- Principles
- Reducing state size
- Memoryless MITM

2 Attacked functions

- Boole
- Edon-R
- EnRUPT
- Sarmal

< E

Principles Reducing state size Memoryless MITM

MITM attacks on hash functions

- find preimage $m = m_1 || m_2$ for h = H(m) with *h* fixed
- alternative view: $H(m) = G(F(IV, m_1), m_2)$
- inversion of g for 2nd component fixed: G⁻¹
- idea: compute many values

 $c_i = F(IV, m_{1,i})$ and $d_i = G^{-1}(H(m), m_{2,i})$

and for random $m_{1,i}$, $m_{2,i}$ and test for $c_i = d_i$

Principles Reducing state size Memoryless MITM

Reducing the "birthday space"

- trivial: birthday space = state space S
- idea: "cheaply" generate intermediate states such that they are from a smaller subspace *T* ⊂ *S*
- "cheaply": must not be more computationally expensive than computing *F* or *G* respectively
- example: words of state fixed to zero

(日)

Principles Reducing state size Memoryless MITM

Memoryless MITM

- CRYPTO 1991 paper by Morita, Ohta and Miyaguchi
- idea: use Floyd cycle finding with switching function

$$r: D \rightarrow \{0, 1\}$$

- F : function in forward, G : function in backward direction
- define step function:

$$s: D \to D, \quad x \mapsto \left\{ egin{array}{cc} F(x) & ext{if } r(x) = 0 \ G(x) & ext{if } r(x) = 1 \end{array}
ight.$$

Principles Reducing state size Memoryless MITM

A closer look at memoryless MITM

- when finding cycle in s, must check whether MITM or cycle in F or G occurred
- restart when cycle in F or G [Pr(restart) = 0.5]
- assumption: output of switching function r equi-distributed
- if *G* is relative costly to compute (computationally) compared to *F* or vice versa, *r* not equi-distributed
- a high ratio here kill memoryless MITM

Boole Edon-R EnRUPT Sarmal

Boole

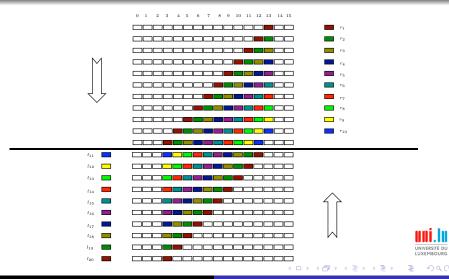

- attacked function: Boole-384/512 [stream based hash]
- size of internal state: 1216 bits (16 + 3 words)
- birthday space: 576 bits (9 words)
- computational complexity: 2288 operations
- memory requirements: 264 blocks
- function withdrawn from competition because of attack

Boole Edon-R EnRUPT Sarmal

Boole MITM

Dmitry Khovratovich, Ivica Nikolić, Ralf-P. Weinmann

Meet-in-the-Middle Attacks on SHA-3 Candidates

Boole Edon-R EnRUPT Sarmal

Edon-R

- attacked function: Edon-R-n [Merkle-Damgård]
- size of internal state: 2n bits
- computational complexity: $max(2^{n-s}, 2^{n/2+s})$
- memory requirements: 2^s blocks
- function not withdrawn

< 17 >

(B) + (B)

Boole Edon-R EnRUPT Sarmal

EnRUPT

- attacked function: EnRUPT-512 [stream based hash]
- size of internal state: 1152 bits
- computational complexity: 2480
- memory requirements: 2³⁸⁴ blocks, needs large look-up tables
- Practical collision attack in next talk!

EnRUPT MITM

Dmitry Khovratovich, Ivica Nikolić, Ralf-P. Weinmann

Meet-in-the-Middle Attacks on SHA-3 Candidates

Boole Edon-R EnRUPT Sarmal

Sarmal

- attacked function: Sarmal-512 [HAIFA design]
- size of internal state: 512 bits (just chaining value)
- computational complexity: max(2^{512-s}, 2^{256+s})
- memory requirements: 2^s blocks
- status: designers consider it a weakness, but not an "attack"
