- 5 Conclusion

# What is complementation property

In DES, if you complement/flip all bits of plaintext and key, then all bits of ciphertext would flip

$$\text{If } DES_K(P) = C \text{ then } DES_{\bar{K}}(\bar{P}) = \bar{C}$$

Results:

- Distinguisher with only two queries
- Reduction of exhaustive key search by factor 2

# Why does it work

Complementation/ All bit flip = difference  $11\dots 11$

- Diff.  $11\dots 11$  in master key  $\Rightarrow$  diff.  $11\dots 11$  in subkeys
- Difference  $11\dots 11$  in the state and the subkey cancel

- 1 Complementation Property
- 2 General Complementation Property**
- 3 Application to Camellia-128
- 4 Application to GOST
- 5 Conclusion

# How to relax the requirements

**Original:** If in Feistel cipher, for **any** key one flips **all** of the bits ...

## Ideas for general:

- Not applicable to all keys, i.e. weak-key class
- Not necessarily flip all the bits

# General complementation

- **Partial-alternating:** Start with  $(\Delta_1, \Delta_2)$  in the plaintext
- **Weak-key:**  $KS(\Delta) \rightarrow (\Delta_1, \Delta_2, \dots, \Delta_1, \Delta_2)$  for some  $K$

# Outcome

## Lemma (Classical Feistel)

*If for  $n$ -bit cipher with  $k$ -bit keys*

$$\exists \Delta : KS(K \oplus \Delta) \oplus KS(K) \xrightarrow{P} (\Delta_1, \Delta_2, \Delta_1, \Delta_2, \dots, \Delta_1, \Delta_2)$$

*Then, if  $p > 2^{-k}$ , distinguisher for a weak-key class of size  $p \cdot 2^k$  exists for the cipher.*

- **Problem:** how to find the differential in the key schedule
- **Result:** RK differential where the state characteristic has probability 1

# Outcome

Modular Feistel = subkeys are modularly added to the state

## Lemma (Modular Feistel)

*If for  $n$ -bit cipher with  $k$ -bit keys*

$$\exists \Delta : KS(K \oplus \Delta) \oplus KS(K) \xrightarrow{P} (\Delta_1, \Delta_2, \Delta_1, \Delta_2, \dots, \Delta_1, \Delta_2)$$

*Then, if  $p \cdot 2^{-\lceil \frac{r}{2} \rceil} (|(\Delta_1)_{n-1}| + |(\Delta_2)_{n-1}|) > 2^{-k}$  and  $2^{-\lceil \frac{r}{2} \rceil} (|(\Delta_1)_{n-1}| + |(\Delta_2)_{n-1}|) > 2^{-n}$ , distinguisher for a weak-key class of size  $p \cdot 2^k$  exists for the cipher.*

- **Problem:** how to find char. in the key schedule with low hamming weight output difference

- 1 Complementation Property
- 2 General Complementation Property
- 3 Application to Camellia-128**
- 4 Application to GOST
- 5 Conclusion

# Specification

Camellia-128 is Japanese CRYPTREC standard

- 128-bit state/key classical Feistel cipher with 2 additional non-linear layers
- 18 rounds
- Key schedule composed of 4 rounds of Feistels and rotations

We analyze the cipher without the non-linear layers !

# Key schedule

- Intermediate key  $K_A$  is obtained from the master key  $K_L$  in four Feistel rounds
- All subkeys are particular 32-bit values of rotations of  $K_A$ ,  $K_L$  on **various amounts**

The difference in the subkey has to be invariant of rotations  $\Rightarrow$  only choice is:

$$\Delta K_L \rightarrow \Delta K_A : 11 \dots 11 \rightarrow 11 \dots 11$$

# Differential in the key schedule

- If we go with characteristic  $11 \dots 11 \rightarrow 11 \dots 11$ , the probability is too low as there are too many active S-boxes
- Switch to differentials:
  - compute the number of characteristics in the differential  $11 \dots 11 \rightarrow 11 \dots 11$
  - compute the lower bound on probability of each characteristic
  - obtain the lower bound on probability of differential

**Result:** the differential has a probability of at least  $2^{-128}$ , i.e. there is on good key

# Applications

- Weak-key class is too small for attack on the cipher
- Switch to hash functions, e.g. Davies-Meyer mode based on Camellia-128
  - The right key/message can be found with  $2^{112}$  encryptions
  - The right message produces collisions for any chaining value (key whitening introduces the right difference at the beginning and cancels the difference at the end)
  - $q$ -differential multicollisions with  $2^{112}$  calls for the *hash* function

- 1 Complementation Property
- 2 General Complementation Property
- 3 Application to Camellia-128
- 4 Application to GOST**
- 5 Conclusion

# Specification

GOST is Russian encryption standard

- 64-bit state, 256-bit key modular Feistel cipher
- 32 rounds
- No key schedule, only word permutations

# Key schedule and differentials

Master key words:

$$K_1, \dots, K_8$$

Subkey words:

$$K_1, \dots, K_8, K_1, \dots, K_8, K_1, \dots, K_8, K_8, \dots, K_1$$

*Probability 1 differential for any difference in the master key words*

# Complementing GOST

Complementation property of GOST has been known and used in previous analysis !

- RK distinguisher with difference  $2^{31}$  in all master key words
- Key-recovery with difference  $2^t$  in all master key words

Attacks that recover the full key have impractical complexity

# Complementing GOST

We use:

- Simple key schedule
- Probability of key schedule differential is 1
- Prob. of one round Feistel with one same active bit in state and subkey is  $2^{-1}$
- If bits cancelled and input is known then subkey bit can be determined

# Key recovery on GOST

- **Data generation:** For each 31 related pair  $(K, K \oplus 2^i)$  encrypt  $2^{32}$  plaintext pairs  $(P, P \oplus 2^i)$
- **Data collection:** For each  $i$  find the pair of ciphertexts  $(C, C \oplus 2^i)$  – 31 pairs in total
- **Domino effect:**
  - Recover 31-bits of the current round (one bit from each of the 31 pairs)
  - Guess the MSB, compute the new state, repeat the process

# Key recovery on GOST

- Framework: related-key attack with 31 related key pairs
- Data complexity:  $31 \times 2 \times 2^{32} \approx 2^{38}$
- Time complexity:  $2^{38}$  (data generation) +  $2^8$  (domino)  $\approx 2^{38}$
- Result: **full 256-bit key recovery**

Both complexities are practicals – our implementation on a PC with a single core and non-optimized code recovered the full key in one day

- 1 Complementation Property
- 2 General Complementation Property
- 3 Application to Camellia-128
- 4 Application to GOST
- 5 Conclusion**

# Conclusion

- General complementation can help finding (easier) RK differential attacks – focus only on key schedule
- #rounds does not matter for classical Feistel
- Applicable to Generalized Feistels as well
- Should not be used to “prove” resistance against differential attacks !

# Conclusion

- General complementation can help finding (easier) RK differential attacks – focus only on key schedule
- #rounds does not matter for classical Feistel
- Applicable to Generalized Feistels as well
- Should not be used to “prove” resistance against differential attacks !
