Cryptography on Embedded Processors

- If software implementation too slow, traditionally cryptographic coprocessors are added
- Instruction Set Extensions (ISE) for cryptography (i.e. addition of custom instructions to general-purpose processor) are an alternative approach
- ISE require less hardware and increase implementation flexibility
- ISE can also be faster than coprocessor solutions
- Case study:
 - SPARC V8-compatible Leon2 embedded processor
 - Implementation of AES with cryptographic coprocessor VS. integration of instruction set extensions

- Coprocessor can process one 128-bit block in 11 cycles.
- AES-128 encryption in different modes of operation supported.

HW overhead	~ 100 %
AES-128 encryption	704 cycles*

* Including time for reading input from memory and writing output to memory.

- Extensions usable for all AES key sizes (128, 192, 256) and all modes of operation
- Support for on-the-fly key expansion

HW overhead	< 10 %
AES-128 encryption	196 cycles*

* Optimized assembly.

For comparison:

AMD Athlon 64 3500+ (64 bit, 3-way super-scalar): 175 cycles / block [2]
